

Clearance Memorandum

Old Place Neck Site (OPRHP No. A08501.002971), Phase III Data Recovery, Staten Island, New York

October 31, 2012

New Jersey-New York Expansion Project

FERC Docket No. CP11-56-000

PAL No. 2367.04

NY SHPO No. 09PR05949

NYCLPC No. FERC / 160-Y

Submitted to:

Spectra Energy Transmission

150 Warren Street

Jersey City, New Jersey 07304

Spectra Energy Corp (Spectra Energy) is proposing to expand its pipeline systems in the New Jersey-New York region to meet the immediate and future demand for natural gas in the largest United States metropolitan area. To accomplish this, Spectra Energy pipeline companies, Texas Eastern Transmission, LP (Texas Eastern) and Algonquin Gas Transmission, LLC (Algonquin) have received a Certificate of Public Convenience and Necessity (Certificate) from the Federal Energy Regulatory Commission (FERC) pursuant to Section 7(c) of the Natural Gas Act (NGA) authorizing the construction and operation of the New Jersey-New York Expansion Project (Project) located in New Jersey, New York, and Connecticut. The NJ-NY Project will create a new transportation path for 800,000 decatherms per day (Dth/d) of natural gas from multiple receipt points on the Spectra Energy systems to new delivery points in New Jersey and New York (Figure 1).

On behalf of Spectra Energy, The Public Archaeology Laboratory, Inc. (PAL) has completed the fieldwork portion of the archaeological data recovery of the Old Place Neck Site (OPRHP No. A08501.002971). The portion of the Project area that underwent data recovery excavations consists of the workspace for the Goethals Bridge horizontal directional drill (HDD) entry point located in the Borough of Staten Island, Richmond County, New York (Figure 2).

Project History

PAL evaluated the archaeological sensitivity of the Goethals Bridge HDD workspace in the archaeological overview survey report filed in December of 2010 and in the first addendum to the archaeological overview survey report, which identified and evaluated Route Variation 50 (Elquist et al. 2010; Elquist and Cherau 2011a). PAL subsequently performed a Phase IB archaeological identification survey of the Goethals Bridge HDD workspace in March and April of 2011 and identified the Old Place Neck Site, which contains both pre-contact and post-contact components

(Elquist et al. 2011). PAL recommended that the Old Place Neck Site was potentially eligible for listing in the National Register of Historic Places (National Register) and that the site be subject to a Phase II archaeological site evaluation; the New York State Historic Preservation Office (New York SHPO) concurred with PAL's recommendation on June 16, 2011 and the New York City Landmarks Preservation Commission (LPC) concurred on May 26, 2011.

In June, July and August of 2011, Phase II site evaluation investigations of the Old Place Neck Site were performed by PAL within and immediately adjacent to the original Goethals Bridge HDD workspace, as it was proposed in Route Variation 50 (Elquist and Cherau 2011b). Following the Phase II investigations, Spectra Energy adjusted the alignment of the Goethals Bridge HDD and reduced the size of workspace corresponding with the boundaries of the Old Place Neck Site. To accomplish this, Spectra Energy realigned the Goethals Bridge HDD entry point approximately 100 ft to the west. This change to the Goethals Bridge HDD workspace and alignment was designated Route Variation 74 and was further described in a third addendum to the archaeological overview survey report (Elquist and Cherau 2011c).

Investigations also took place at the adjacent yard associated with Spectra Energy's existing metering and regulating station 058 (M&R 058) and included a soil boring performed within its boundaries in December 2010. The yard was assigned high sensitivity for the presence of deeply-buried archaeological resources (Cherau 2011). However, since the M&R 058 yard (identified as Yard #8 in the archaeological overview survey report [Elquist et al. 2010:6 and 108]) was an existing graveled surface and no grading/excavation activities would be required during construction, no further archaeological investigations were recommended for this yard. However, while evaluating viable alternatives for Route Variation 74, Spectra Energy requested that PAL perform a Phase IB archaeological identification survey within the entire yard to determine if alternate pipeline routing and/or facility modifications could be situated in the area. These alternate pipeline routing options and facility modification locations were not adopted and Route Variation 74 was ultimately selected.

The soil boring located in the M&R 058 yard (RCH-1-ARC-1) revealed the presence of archaeologically sensitive strata, and a Phase IB archaeological survey of the M&R 058 yard in the form of machine-assisted trenches was recommended (Cherau 2011:6). To evaluate the potential alternate routing of the proposed pipeline and M&R 058 facility modifications, PAL performed Phase IB machine-assisted testing in August of 2011 within the limits of the yard. The results and recommendations of the additional Phase IB testing at the M&R yard 058 and Phase II evaluation were presented in one report (Elquist and Cherau 2011b).

PAL concluded in this report that Old Place Neck Site deposits were present in both the Goethals Bridge HDD workspace and M&R 058 yard areas. It was recommended that the pre-contact component of the site was eligible for listing in the National Register under Criterion D (36 CFR 60). Project plans indicated that proposed construction activities and workspace associated with the Goethals Bridge HDD would impact the Old Place Neck Site, and PAL recommended that measures to minimize or mitigate the adverse effects should be considered in consultation with the New York SHPO, LPC and other interested stakeholders and Native American groups who have requested to be consulting parties for the Project. In a letter dated January 12, 2012 the LPC concurred with the findings and recommendations of the report. The New York SHPO also concurred (Letter dated December 13, 2011), but expressed concerns that there could be as yet unidentified "shaft features" associated with the post-contact component of the site, which could

potentially contain significant information. PAL recognized the concerns of the New York SHPO regarding the post-contact component of the site, which were considered in the technical proposal per New York SHPO's opinion.

On March 19, 2012, PAL submitted a draft Phase III data recovery proposal to the New York SHPO and LPC for review. On March 29, 2012, LPC responded, concurring with the proposal; LPC also recognized that the proposal includes suggestions for public outreach, however the methodology will be determined after the fieldwork component of the data recovery is completed. On April 20, 2012, the New York SHPO provided comments on the proposal. New York SHPO offered comments regarding the following components of the proposal: 1) curation; 2) public dissemination of results; and 3) reporting. Subsequent to the submittal of this revised proposal, the Goethals Bridge HDD workspace (adopted as Route Variation 74) was revised by Spectra Energy back to the larger Route Variation 50 footprint in consideration of comments made by the FERC. Therefore, PAL prepared a third revised technical proposal submitted to the New York SHPO and LPC for review on May 16, 2012. The LPC (Letter dated May 23, 2012) and New York SHPO (Letter dated June 21, 2012) responded concurring with the technical methodology of the proposal and made recommendations regarding expansion of the public dissemination of research results.

Summary of Previous Investigations of the Old Place Neck Site

Goethals Bridge HDD Workspace

The Phase IB investigations of the Goethals Bridge HDD workspace was undertaken in March and April of 2011 and included a walkover inspection and subsurface hand testing involving the excavation of 64, 50-centimeter (cm) diameter test pits, one 0.5-x-1-meter (m) excavation unit (EU), and three 1-x-1-m EUs. Test units were placed throughout the proposed workspace, as well as to the north and east of the workspace. Pre- and post-contact archaeological components were identified, and designated the Old Place Neck Site (Elquist et al. 2011). Testing yielded 27 pieces of chipping debris of chert, Normanskill chert, and jasper; three bifaces of chert, Normanskill chert and an unidentified metamorphic material; two chert utilized flakes; and a stemmed argillite projectile point. A possible PaleoIndian occupation as the site is represented by the recovery of a jasper channel flake. The argillite point is most consistent with the Late Archaic Bare Island type. The finds of Normanskill chert chipping debris and biface fragment were recovered from a single unit, suggesting an individual episode of late stage stone tool manufacture or maintenance.

Post-contact finds included structural debris identified during the walkover inspection, and the recovery of 1,645 pieces of post-contact material during subsurface testing. The area of structural remains consisted of linear, subtly bermed areas of concentrated brick deposits and demolition debris containing structural materials, and other post-contact items. The patterning of the demolition debris and brick deposits suggested that at least some approximation of the original footprint of the structure could remain. Based on stratigraphic observations for this location, the area was plowed prior to the structure being built.

Post-contact materials recovered during Phase IB testing include ceramics, kaolin and ball clay smoking pipes, brick, glass, metal (nails, hardware, copper, unidentified), leather, coal and coal by-products, plaster/mortar, gunflints, slate, modern debris (plastic, rubber and styrofoam), and other material that may consist of paint fragments. The diagnostic ceramics indicated eighteenth- and nineteenth-century occupations. Copper items were also recovered that include two unidentifiable

fragments, a small decorative, tear-drop shaped piece of sheet copper, and a wire ring with a hook-like projection. When considered together with the other early items, such as the gunflints and diagnostic ceramic sherds, it was considered that the copper pieces (ring, tear-drop shaped sheet copper, and fragments) may have a contact/colonial period affiliation.

Diagnostic post-contact materials associated with structural remains and underlying plowzone suggested an early to mid-nineteenth century date of construction. Overlay of the 1874 Beers map onto a modern aerial photograph indicated the structure represents a building located towards the rear of the historic parcel. Evidence of a decorated plastered interior suggests that the building was not a simple shed or outbuilding.

The Phase IB investigations indicated both the pre-contact and post-contact components of the Old Place Neck Site were potentially significant archaeological resources and a Phase II site evaluation was recommended (Elquist et al. 2011:67). Phase II investigations of the Goethals Bridge HDD workspace were subsequently undertaken during June, July and August of 2011 (Elquist and Cherau 2011b), and involved the excavation of 335, 50-x-50-cm test pits along a 5-m interval grid oriented to 44° magnetic north, and 20, 1-x-1-m EUs (Figure 3).

A total of 514 pieces of pre-contact Native American artifacts were recovered including lithic debitage, bifaces, aboriginal ceramics, a core fragment, FCR, a graver, a hammerstone, projectile points, unmodified lithic raw material, a scraper, unifaces, utilized flakes, calcined bone, and a shell fragment. The presence of large amounts of chipping debris in one unit indicates the presence of a lithic workshop area which also contained a Late Archaic Narrow-stemmed point. Several features including possible postmolds, and four small pits (fire/cooking pits) were also identified that produced radiocarbon ages dating to the later Middle Woodland, Late Woodland and Contact periods. Diagnostic artifacts included various Late Archaic Narrow-stemmed projectile points of argillite, a Transitional Archaic Nyack side-notched point of chert, and Woodland period ceramic fragments.

The Phase II site evaluation of the pre-contact component indicated the presence of relatively discrete deposits representing several individual occupation episodes at the site. The deposits displayed relatively good integrity. Temporally diagnostic artifacts and radiocarbon dates from features indicate that occupations at the site consist of both short-term and possibly longer duration stays spanning the Late Archaic through Contact periods. Cultural materials recovered from the site are suggestive of hunting, the cooking and processing of food, the processing of other materials, and the maintenance and manufacture of tool kits.

Post-contact materials from the site include 6,165 items of ceramics, glass, metal, brick, coal and coal by-products, miscellaneous building materials and personal items. The wide variety of ceramics generally date to the eighteenth- and nineteenth-centuries, and indicate the site was most intensively used during the early nineteenth-century. One glass item of note includes what appears to be a knapped glass shard made from bottle glass manufactured between 1750 and 1860. Other items of note include fragments of copper possibly indicative of a contact/early colonial Native American component, and personal items that include gunflints, worked ballast, ball clay smoking pipes, slate pencils, an eighteenth-century boot or garter buckle, and an American Naval military button likely pre-dating 1830.

The Phase II assemblage and archival research demonstrated that EuroAmerican occupation at the site began by the 1680s. Past activity at the property included agriculture during the eighteenth-through nineteenth-centuries and operation of the Old Place Mill during the nineteenth century. Phase II investigations of the structural remains at the site indicate it was likely built around the same time as the Old Place Mill, and likely used as quarters for mill workers that included slaves and Native Americans. The find of a knapped glass uniface likely dating to the early nineteenth-century supports later historic activity at the site by Native Americans. Use of the structure as a domestic site likely ceased after the mid-nineteenth century, though it may have continued to be maintained and used as a storage/outbuilding until being razed in the early twentieth century which appears to have left little archaeologically visible traces. No approximation of a structural footprint was observed during the Phase II investigations.

M&R 058 Yard

In December of 2010, geoarchaeological soil boring RCH-1-ARC-1 was undertaken within the M&R 058 yard area. The boring revealed archaeologically sensitive fill strata from about 40 centimeters below ground surface (cmbs) (1.3 ft) beneath a compact asphalt and fill overburden to about 160 cmbs (5.2 ft) for post-contact period resources, and from 160 (5.2 ft) to at least 235 cmbs (7.7 ft) in natural deposits for pre-contact period resources (GRA 2011:15-16, 26, 40 [Attachment A in Cherau 2011]). Given the presence of compact asphalt and gravel (parking lot overburden) fill and sensitive archaeological strata that could extend to at least 235 cmbs (7.7 ft deep), PAL recommended that Phase IB survey be undertaken within the yard using machine-assisted trenches (Cherau 2011).

Phase IB testing subsequently undertaken within the yard in August 2011 revealed four to five layers of fill overlying plowzone (Apz) and intact subsoils (Elquist and Cherau 2011b). Eight, 2.5-x-5-m (8.2-x-16.4-ft) machine-assisted trenches and two hand-excavated 50-cm diameter test pits were excavated (see Figure 3). None of the fill deposits are considered to have any meaningful archaeological or stratigraphic contextual integrity. The underlying Apz and intact B horizon sediments, however, contain pre- and post-contact materials that retain stratigraphic integrity in terms of their depositional history. Pre-contact materials identified during the machine testing included chipping debris of jasper, chert, basaltic rock and quartz, a jasper biface fragment and one possible feature. The jasper tool fragment was recovered from locally derived redeposited topsoils and subsoils. The possible feature consisted of a dark patch of soil within intact B horizon soils that was round in plan (30-x-35-cm) and 22 cm thick that contained a piece of basaltic rock chipping debris, and fragments of brick and slag. Its regular morphology suggests a cultural origin, but the presence of post-contact materials and a root cast through the feature suggests it may be the result of natural processes such as bioturbation. The lack of radiocarbon datable materials prevented further analysis.

Post-contact materials recovered from the machine trenches include ceramics, glass, metal, brick, pieces of shell and wood, coal and coal by-products, stone building materials, and more recent modern debris such as plastic and asphalt. The bulk of the materials were recovered from fill deposits lacking archaeological or stratigraphic integrity. Materials recovered from the underlying plowzone include brick fragments, ceramic sherds, glass, shell, and coal/slag. Ceramic types from the Apz include redware, porcelain, ironstone, pearlware, whiteware, and American salt-glazed stoneware. Overall, the plowzone assemblage includes items dating from the late eighteenth through early twentieth centuries and represents spatial continuation of plowzone deposits

associated with the post-contact occupation of Old Place Neck Site to the south and east. The presence of the pre-contact materials in Apz and B horizon deposits also indicates that the pre-contact component of the Old Place Neck Site continues from the south and east into the M&R 058 yard area. As such, the site deposits from the M&R 058 yard area are also considered significant together with those from the above described deposits at the Goethals Bridge HDD workspace (Elquist and Cherau 2011b). Given the large percentage of testing (19 percent) that has already been undertaken along the APE in the M&R 058 yard area, and paucity of materials from trenches along the proposed pipeline trench, no data recovery excavations were proposed for this location.

Archaeological Data Recovery

Phase III archaeological investigations were conducted in accordance with stipulation III of the Programmatic Agreement (PA) developed in consultation with the New York SHPO, the LPC, the Federal Energy Regulatory Commission (FERC) and Spectra Energy. Archaeological investigations were conducted in consultation with the New York SHPO and LPC, and in compliance with the guidelines set forth in FERC's Office of Energy Project's *Guidelines for Reporting on Cultural Resources Investigations* (2002), the Secretary of the Interior's *Standards and Guidelines for Archaeology and Historic Preservation* (NPS, 48 Fed. Reg. 44716-42, Sept. 29, 1983); the standards and guidelines set forth in *Standards for Cultural Resource Investigations and the Curation of Archaeological Collections in New York State* (New York Archaeological Council [NYAC] 1994) adopted by the OPRHP; and the standards and guidelines set forth in *Landmarks Preservation Commission Guidelines for Archaeological Work in New York City* (LPC 2002). Because of the sensitive nature of some of the material contained in this report, the covers and any applicable pages are labeled "CONTAINS PRIVILEGED INFORMATION – DO NOT RELEASE" in accordance with FERC guidelines and 36 CFR 800.11(c)(1).

By definition, a data recovery program "is the systematic removal of the scientific, prehistoric, historic and/or archaeological data that provide an historic property with its research or data value" (36 CFR Part 66). A data recovery program impacts a site. Significant data are, however, recovered for analysis and dissemination. Because a site can be partially or wholly destroyed in the course of archaeological mitigation, the data recovery program must include adequate methodologies to deal with anticipated discoveries and their removal from original environmental and cultural contexts. The Phase III data recovery program provided for the collection of data, the processing, analysis, and curation of artifacts and samples, and archival storage of notes, drawings, photographs, and other records generated by the excavations. These activities addressed research questions and hypotheses and provided ways in which the general public can benefit from the Phase III data recovery program.

PAL staff involved in the project include Deborah Cox (President/Senior Project Manager), Greg Dubell (Energy Project Manager), Suzanne Cherau (Principal Investigator), and Ora Elquist (Project Archaeologist), assisted in the field by a team of qualified archaeologists. The on-site laboratory processing and cataloguing was overseen by Heather Olson (Laboratory Supervisor) with the assistance of Caitlin Lackett (Archaeologist/Lab Analyst), and Amelia Bidwell (Archaeologist/Lab Assistant). The fieldwork for the data recovery program at the Old Place Neck Site was conducted from July 9 to September 27, 2012. All recovered materials were processed and cataloged at the on-site field laboratory office before being brought back to the PAL laboratory facility in Pawtucket, RI where they will undergo additional analysis.

Data Recovery Program Methodology

The field and laboratory methodologies developed for the Phase III data recovery program were designed to aid in the collection of as many classes of data as possible. These methodologies were used to systematically excavate, record, process, and analyze identified cultural deposits. This section details the different procedures that were followed during the data recovery within the Old Place Neck Site area.

The data recovery field investigations were conducted exclusively within the Goethals Bridge HDD workspace, which consists of an approximately 72,518 square feet (sq ft) (6,737 square meters [sq m]) construction area within which all construction-related impacts will occur. No subsurface testing was undertaken during the Phase III investigations outside of the workspace (Figure 4). PAL proposed excavation of a 10 percent sample of the site within the workspace boundaries. The combined Phase IB and Phase II testing within this area totaled 90.25 sq m, which was originally estimated in the data recovery proposal as totaling a 1 percent sample of the site within the workspace, but which actually totals a 1.3 percent sample (Table 1). In order to collect adequate data for analysis, PAL excavated an additional 588 sq m (8.7 percent) of the site area within the APE for the Goethals Bridge HDD workspace, bringing the total testing to 10.06 percent (678.25 sq m) of the site within the APE at this location (see Table 1).

Field Methodology

The first step in the fieldwork portion of the Phase III data recovery was the establishment of a primary N0E0 site datum within the portion of the Old Place Neck Site that lies within the workspace area. This datum was located at the site of Phase II test pit N0E0. All data recovery test units were designated with coordinates relative to the site datum, which also allowed all previously excavated units to be located and linked with the Phase III data recovery units. A secondary datum was also established to serve as a permanent reference point.

Phase III testing units consisted of one 0.5-x-2-m; 19, 1-x-1-m; 24, 1-x-2-m; and 130, 2-x-2-m excavation units (EUs). The 2-x-2-m EUs were excavated in 1-m quadrants (Table 2, see Figure 4). The majority of units were configured into blocks designed to investigate areas of artifact concentrations identified during the Phase II investigations. Excavation proceeded in 5-centimeter (cm) levels within natural levels with the exception of plowed soils, which meets or exceeds New York Archaeological Council (NYAC) guidelines adopted by the New York SHPO (NYAC 1994). Plowed soils were removed as a single stratum. The EUs were placed and configured as needed to enable the complete excavation of features, to further explore concentrations of cultural materials, or to accommodate limited access areas around trees, etc. The placement of EUs was guided by a number of concerns: artifact/debitage density, spatial distributions of different kinds of artifacts, and identified cultural features. The testing goal of the Phase III data recovery program was to concentrate the excavation effort in areas that would yield optimal contextual information for the site.

Soils were screened through ¼-inch hardware cloth. When features or concentrations of archaeological material were encountered, plan drawings were recorded with Munsell soil color and texture descriptions. Measured profiles were drawn of each feature and of at least one wall of the excavation units. The three-dimensional provenience of diagnostic artifacts was recorded where

possible. Excavation notes were kept for each excavation unit and feature supplemented by the scaled profile and plan drawings. Photographic records were recorded in digital format.

Feature soil samples were brought back to the PAL laboratory facility in Pawtucket, Rhode Island for analysis, flotation, and characterization studies. Any remaining feature soil not collected as a soil sample was screened through 1/8-inch mesh at the site. Column samples were taken as appropriate, and will be processed for control purposes and archived for future soil studies. Charcoal samples from cultural features were collected for radiocarbon dating. Archaeological materials and samples were bagged and tagged according to unit, quadrant, strata, depth, and/or features.

Due to the large amount of post-contact material expected to be present within the plowzone, a collection strategy for certain materials was developed. The following materials were identified, counted, and noted on excavation unit forms, but not saved for further laboratory analysis: coal and coal by-products and slag; shell; unidentified metal fragments (except for suspected copper and brass); structural materials (brick, mortar, nails, window glass); and modern debris (e.g. plastic, styrofoam). Representative samples of whole or brick fragments were collected from the previously identified surface structure to allow for possible data through comparative analysis. With the exception of the brick samples from the structure, these materials were considered redundant and not likely to yield new information given the similar types and amounts recovered during the previous investigations at the site. All other post-contact materials were collected for laboratory processing and analysis. A sampling strategy was developed for fire-cracked-rock (FCR) at one block where deposits were particularly dense. The FCR from this area was collected in its entirety in the field, described, counted and weighed in the lab, and then a 10 percent sample of the material was saved for further analysis.

Laboratory Processing and Analyses

Recovered cultural materials from the Old Place Neck Site were processed and catalogued at the on-site field laboratory (secure climate controlled trailer at the project work site). All cultural materials and samples were organized by provenience and then logged into the PAL laboratory system. Artifacts were sorted by type and cleaned immediately with tap water or dry brushing depending on the material type and condition. Artifacts selected to undergo residue analysis were not washed. Artifact processing (sorting, logging, and cleaning) has been completed for 100 percent of the Phase III assemblage. Cataloging is still ongoing, and the catalog included with this memo includes approximately 95 percent of the site assemblage. Following the completion of fieldwork and cataloging, the materials will be brought back to the PAL laboratory facility in Pawtucket, Rhode Island for additional analysis and curation measures.

Following the initial laboratory processing, all cultural materials recovered were cataloged using a custom-designed *Microsoft Access* relational database. In the cataloging process, artifacts from each provenience were grouped based on material and function. For example, lithic chipping debris was sorted by size, presence or absence of cortex, and raw material. Materials with the same characteristics were grouped, cataloged, and bagged together. All diagnostic pre-contact materials and all tools were cataloged and bagged individually. Attribute data for pre-contact materials and tools were recorded on a specially designed analysis screen within the PAL cataloging system. Post-contact materials were also grouped and cataloged by material and function. Special attention was paid to diagnostic characteristics of ceramics and glass, such as maker's marks or decoration

techniques, which may provide a range of occupation or use for a historic site. The PAL database allows for extensive data manipulation and analysis based on provenience, raw material, function, artifact type, artifact density, decoration technique and other factors.

Further studies to be conducted on the materials and samples from the Old Place Neck Site data recovery include processing and analysis of soil samples, radiocarbon dating, and other specialized analyses. Representative flotation samples from feature soils and control column samples as appropriate will be processed using the Model A Flote-Tech machine, which utilizes a multi-modal flotation technique. The system is portable and uses water recirculation in a closed loop between a water reservoir and a flotation tank. Provision is made for removing the residue from the system without loss of water from the loop. A method of incorporating aeration into the water makes the flotation process more efficient than conventional techniques. Using the system's baffle, objects having a specific gravity slightly greater than water are removed easily. Two mesh sizes are used in the system, a coarse fraction screen measuring 1.0 mm in size and a fine fraction screen measuring 0.33 mm in size. Following this process the recovered material will be divided into a heavy and a light fraction. The fractions will then be scanned using both an illuminated desk magnifier fitted with a 3-diopter lens (1.75x magnification) and an Olympus zoom stereo microscope Model SZ-Tr with magnification ranges of 7x to 40x. Recovered materials will be documented, separated into plastic vials and labeled. These materials will be scanned for a variety of data classes that could include carbonized seeds and nuts, bones, pottery, charcoal, and microflakes. The PAL laboratory staff perform the sorting and cataloging of seeds, nuts, microflakes, and any other cultural materials collected through flotation. Additional specialized analyses will be undertaken of selected soil samples including samples collected for pollen, phytolith and starch analysis, and FTIR analysis.

Features containing datable material were encountered at the site, and charcoal samples from each feature were collected in the field and returned to PAL for pre-processing. Thus far, one radiocarbon sample has been processed and submitted. Additional radiocarbon samples will be cleaned, weighed, packaged, and sent to Beta-Analytic Laboratories in Florida for dating. Where collection of the standard sample size for radiocarbon dating is not feasible, a smaller sample will be processed as an AMS (Accelerator Mass Spectrometry) date.

Other types of specialized analyses that will be undertaken include depositional, lithic, residue and metallurgical analyses, the results of which will be provided upon their completion in the technical report. Depositional analyses will include the density, diversity and spatial (horizontal and vertical) distribution of cultural materials, as well as the possible function and deposition of features. Lithic analysis will include classification of debitage by type (flake or shatter), raw material type and possible sources, size, color and weight, and other attributes indicative of manufacturing stages. Stone tools will undergo use-wear analysis, and selected artifacts will undergo residue analysis. Selected copper items with a suspected Contact/early colonial period affiliation will undergo metallurgical analysis.

Curation

PAL has approached the Staten Island Institute of Arts and Sciences (repository for the Old Place Neck Site artifact collection excavated by the Andersons in the 1960s) to be the permanent repository for the Old Place Neck Site materials. All recovered cultural materials and related documentation (e.g., field forms and notes, maps, photographs, report) will be processed in accordance with the

requirements of the permanent repository, including organization and storage in acid-free Hollinger boxes with box content lists and labels printed on acid-free paper. These boxes will be temporarily stored at PAL according to curation guidelines established by the Secretary of Interior standards 36 CFR 79, as well as in accordance with *Standards for Cultural Resource Investigations and the Curation of Archaeological Collections in New York State* (NYAC 1994) and LPC guidelines (2002) until the New York SHPO and LPC concur with the final report for the Phase III data recovery investigations.

Results

Soil profiles observed at the site were consistent with that recorded during the PH II investigations. Most typically, profiles observed at the site consisted of a surface organic duff or Ao horizon underlain by a black (10 YR 2/1) to very dark grayish-brown (10 YR 3/2) silty fine to medium sand developing A horizon situated above a very dark grayish-brown (10YR 3/2) to brown (10YR 4/3) plowzone (Apz) of silty medium sand. The developing A consists of an organics-rich horizon that has developed with the uppermost centimeters of the Apz stratum since plowing has ceased at the site. The Apz is underlain by intact soils typically consisting of a strong brown (7.5 YR 5/6) silty medium sand B₁ horizon that overlay a B₂ horizon of strong brown (7.5YR 5/8) to yellowish-red (5YR 5/8) silty sand that was often slightly coarser than the overlying soils. In some units a lighter C horizon of light brown (7.5YR 6/4) of silty sand or sand with trace of silt was encountered. It was also noted that natural rock inclusions in the soil were rare, and generally limited to occasional small, rounded pebbles, and chunks of sandstone that were generally encountered at deeper levels within the soil column. The sandy subsoils below the Apz were generally undisturbed, though bioturbation (tree-throws, roots) was commonly encountered.

At the location of razed structural remains (Block 13 – see Figure 4), the soil profile varied slightly from the rest of the site. A layer of demo fill consisting of brick and mortar deposits mixed with very dark grayish-brown silty sand was observed overlying the typical profile of Apz and intact B subsoils seen elsewhere at the site. A thin layer of this deposit was also observed in EU 112, the southernmost unit of Block 6 (see Figure 4).

In all, the Phase III excavations resulted in the recovery of approximately 9496 pieces of pre-contact cultural material, and approximately 14,826 pieces of post-contact cultural material. Items classified as temporally neutral (e.g calcined bone from plowzone soils, charcoal samples) were also recovered. The types of cultural material are summarized by excavation area below.

Block 1

Block 1 is located within the northwest portion of the workspace and is comprised of seven 2-x-2-m EUs (EUs 1 through 4, 26, 27 and 47) (see Figure 4). The Block is situated at the location of Phase II, EU 1 where a possible post-contact pit feature designated Feature 1 was identified. Phase III EUs were laid out around Feature 1 and the upper 10 cm removed (Ao and Developing A horizon) which more fully exposed the “pit” in plan, which was also designated Feature 1 for the Phase III investigations. Feature 1 exhibited an ovoid outline measuring 223-x-264 in plan, and its irregular morphology suggested it may not be cultural. Further excavation revealed that the boundaries of Feature 1 expanded and contracted in plan and profile as excavations went deeper. These irregularities confirmed that the soil anomaly designated Feature 1 was in fact due to a tree throw and not cultural in origin. As such, cultural materials recovered from the soil anomaly have been

redeposited. Block 1 also contained extensive evidence of bioturbation on the form of root disturbance which also had clearly moved materials deeper into the subsoils underlying the Apz.

The additional units at Block 1 were subsequently excavated to further explore what appeared to be a light to moderate scatter of pre-contact materials. In all, pre-contact materials recovered from Block 1 numbered 134 items and included a sandstone abrader, four argillite bifacially-flaked tools (bifaces), six pieces of fire-cracked rock (FCR), a manuport, two projectile points, an argillite utilized flake, two pieces of lithic raw material of argillite and quartz, and pieces of debitage (see Table 3). Two shell fragments were also recovered from B horizon soils suggesting a pre-contact affiliation, though the extensive bioturbation observed at Block 1 indicates that they could have been introduced deeper into the soil column through natural means.

The projectile points consist of a Late Archaic Narrow-Stemmed (c.f. Bare Island variant), and a small Late Woodland triangle point, both manufactured from argillite. A wide variety of lithic material types is represented in the debitage assemblage (see Table 3), which is dominated by argillite followed by chert and jasper. The pre-contact artifact assemblage from Block 1 indicates overlapping Native American occupations dating to the Late Archaic and Late Woodland periods. The deposits were generally low density in nature, but occurred most frequently in EUs 2 and 4. The deposits indicate temporary occupations that involved hunting and late-stage stone tool manufacture and/or maintenance.

A total of 466 pieces of post-contact cultural material were recovered from Block 1 and included ball clay smoking pipe fragments, ceramic sherds, copper items, glass, and personal items (Table 4). Ceramic sherd types include redware, Staffordshire slipware, Jackfield earthenwares, porcelain, creamware, ironstone, pearlware, whiteware, yellowware, and stonewares. Whiteware was the most frequently represented type of ceramic sherd recovered. In addition to remains of smoking pipes, personal items include copper and glass buttons, a copper spoon, a slate pencil, a gunflint, a silver coin, and a metal boot or garter buckle. The coin consists of a U.S. "half dime" with a Heraldic Eagle design and was likely minted in Philadelphia between 1800 and 1805. Diagnostic ceramics from the Block 1 post-contact assemblage largely range in date from the eighteenth through nineteenth centuries.

Block 2

Block 2 is made up of 21 EUs, and situated within the northern end of the workspace (see Figure 4). A concentration of pre-contact cultural materials was identified at this location during the Phase II investigations. The pre-contact assemblage at Block 2 consisted of 957 artifacts and two possible features. Pre-contact materials recovered from Block 2 include an aboriginal ceramic sherd, seven bifaces, 760 pieces of chipping debris, a chert core, an argillite drill or perforator, 91 pieces of FCR, a calcined bone fragment, one hammerstone, 6 manuports, 13 projectile points, 70 pieces of raw material, two argillite unifacially-flaked tools (unifaces), and three argillite utilized flakes (Table 5). The ceramic sherd is sand tempered. All the bifaces except one were manufactured from argillite. The remaining biface was manufactured from basaltic rock. Like Block 1, a wide variety of lithic material types are represented in the debitage assemblage (see Table 5). Argillite was the most frequently occurring type of chipping debris, followed by jasper and chert. Diagnostic projectile point types include 11 Late Archaic, Narrow-Stemmed points, one chert Levanna point, and one jasper point consistent with the Sand Hill Stemmed type as described by Funk (1979). Based on the thickness of the stem which exhibits the cortex of the pebble or small cobble from

which the point was made, the point is probably best characterized as a Lamoka point affiliated with the Late Archaic period. The Narrow-Stemmed points are all manufactured from argillite (extremely weathered), and are consistent with the Late Archaic Bare Island tradition. The Levanna point was manufactured from a Hudson Valley chert and indicates a Late Woodland period occupation. The majority of the raw material consists of argillite and was likely brought to the site from source areas in New Jersey. The count of argillite raw material is likely overrepresented in the assemblage given the highly weathered and fragmentary nature of the argillite encountered at the site. Deposits of this were frequently recovered from one area in multiple pieces, and several of the pieces may in fact be tools, but are so weathered or fragmentary that any evidence of modification is no longer visible.

Two soil anomalies encountered at Block 2 were designated Feature 6 and Feature 15. They are thought to possibly represent small, pre-contact pit features. Feature 6 was first identified as a small, very subtly reddened area of soil in the NE quad of EU 31 at 70 centimeters below the surface (cmbs) (see Figure 4). Leaching of the sandy soils at the site made visual identification of potential features difficult. A portion of the feature along the east edge of EU 31 had been removed through excavation of adjacent EU 29. As visible in EU 31, the feature measured 40-x-75-cm in maximum horizontal dimension, and exhibited a fairly regular round shape. Feature 6 had a shallow bowl-shape in profile that extended 15 centimeters in depth. Feature 6 soils were screened separately from the surrounding matrix as soon as these soils were visually identified, and produced seven argillite flakes. No cultural materials were present at this depth in the adjacent surrounding subsoils. It's possible that Feature 6 represents an area of bioturbation where cultural materials were introduced from above into underlying subsoils, though its regular round morphology is suggestive of a cultural origin. No charcoal was present in Feature 6 soils, but the presence of the argillite flakes (given the relatively large number of Late Archaic points all of argillite) suggests a possible Late Archaic affiliation.

Feature 15 was first identified just below the Apz in the NW quad of EU 88 (see Figure 4). Feature 15 soils consisted of a very regular round patch of darker organic soil measuring 38 cm in diameter in plan. The feature exhibited a bowl-shaped profile that measured 17 cm thick. Artifacts recovered from Feature 15 include two jasper flakes, a piece of calcined bone, and a whiteware ceramic sherd. The whiteware sherd may be intrusive given the presence of numerous sizeable roots observed running through the feature. The feature is interpreted as representing a possible pre-contact pit feature. No charcoal, diagnostic artifacts, or other radiocarbon datable material was present in the feature. Analysis of soil samples collected from this feature may yield additional data.

Preliminary observations of the distribution of the pre-contact materials at Block 2 indicate the presence of three concentrations. The westernmost concentration of materials (largely derived from EUs 29 and 31 – see Figure 4), contained a substantial amount of the jasper debitage, a manuport, biface, a light scatter of FCR, argillite Narrow-Stemmed projectile points, and Feature 6. A second concentration of materials was observed in EUs 5, 7, and 12 (see Figure 4). Deposits at this concentration include debitage of argillite, chert and jasper, argillite Narrow Stemmed points, the chert Levanna point, the drill/perforator fragment, and flakes of basaltic rock and sandstone that may be associated with groundstone manufacture and/or maintenance. Deposits of FCR at this location were far less prevalent than observed in the concentration to the west. The easternmost concentration of pre-contact material was largely derived from EUs 30, 88, and 92 (see Figure 4). Deposits in this area include debitage of mainly jasper, argillite and chert, a Narrow-Stemmed projectile point, a light scatter of FCR and Feature 15.

The pre-contact assemblage from Block 2 appears to represent multiple, overlapping occupation episodes dating to the Late Archaic, and Late Woodland periods. Given the presence of the Lamoka point and relatively large number of Narrow-Stemmed points, the majority of these occupations are expected to date to the Late Archaic period. There is a somewhat wider variety of chipped stone tools at Block 2 compared to Block 1. The occupations at Block 2 indicate hunting, stone tool maintenance and limited processing activities took place. The presence of the core and chunks of lithic raw material suggest that lithic manufacturing also took place at this location.

Post-contact materials recovered from Block 2 numbered 890 items that include ceramic sherds, items of copper and lead, glass, and a variety of personal items (Table 6). Types of ceramic sherds include redware, slipware, earthenwares, porcelain, creamware, ironstone, pearlware, tin enamel ware, whiteware, yellowware, American stoneware, English Brown stoneware, and Nottingham/Burselem stoneware. Personal items include ball clay smoking pipe fragments, a copper penny with a possible Indian Head design, buttons of copper, glass, and a ferrous material, a cuprous grommet possibly from a shoe, a lead bullet, and a slate pencil. The diagnostic ceramics in the post-contact assemblage from Block 2 typically range in date from the eighteenth through nineteenth centuries.

A post-contact feature (designated Feature 2) was also identified that consisted of an irregular ovate patch of dark Apz-like soil that measured 28-x-60 cm in maximum horizontal dimension, and extended 10 cm deep into the surrounding B₁ soils just below the plowzone. In profile, Feature 2 had a shallow flattened bowl-shaped profile. Screening of Feature 2 soils yielded one whiteware ceramic sherd. Soils at this location were substantially compacted and the plowzone quite thin compared to other areas of the site, and a cartpath is suspected to have been present in this area. As such the feature is thought to possibly represent a wheel rut that impressed topsoils down into the underlying B horizon soils.

Block 3

Block 3 is located north of Block 1 (see Figure 4), and was laid out and excavated in order to further explore the area that contained possible Native American pit features (designated Features 2 and 3) identified during the Phase II investigations. Features 2 and 3 produced Contact period and Late Woodland period radiocarbon dates of 260 ± 30 B.P. and 690 ± 30 B.P., respectively. Three excavation units were laid out around the Phase II units that contained the feature to the east, west and south, but not to the north as this area lies along the boundary of the APE.

Pre-contact deposits recovered from Block 3 were extremely sparse consisting of one flake each of argillite, jasper and quartzite (Table 7). No additional features were identified. Recovered post-contact materials were also sparse relative to other areas consisting of 45 pieces of cultural material that include ceramic sherds, glass and ball clay smoking pipe fragments (Table 8). The glass assemblage included a partial medicine bottle that dates to 1875. Ceramic types include redware, slipware, porcelain, creamware, pearlware, earthenwares, whiteware, and yellowware. The diagnostic ceramics typically exhibit manufacturing date ranges from the eighteenth and nineteenth centuries.

The pre-contact deposits consist of a very light lithic scatter suggestive of lithic maintenance activities. The deposits may also represent the outer edges of the concentrations of pre-contact materials to the south and east. The paucity of pre-contact artifacts in this area indicates that the

feature identified during the Phase II investigations likely represents a brief occupation episode that left a minimal footprint of activity.

Block 4

Block 4 is located near the northeastern corner of the workspace and is comprised of 22 EUs (see Figure 4). It was situated to further explore a concentration of pre-contact materials identified during the Phase II investigations. A total of 1,189 pieces of pre-contact cultural material were recovered from Block 4 that included debitage, chipped stone tool, and non-chipped stone items. There is a wide variety of lithic material types present in the debitage or chipping debris assemblage including argillite, basaltic rock, chalcedony, chert, hornfels, jasper, quartz, quartzite, and sandstone. The debitage assemblage was dominated by argillite followed by jasper and chert (Table 9). The flakes of basaltic rock and sandstone could be related to groundstone tool production and/or maintenance. The chipped stone tool assemblage from Block 4 includes 13 bifaces, three cores, four drills, 35 projectile points, two scrapers, six unifaces, and six utilized flakes (Table 10). The projectile points predominantly consist of argillite Narrow-Stemmed types (N=22). Other diagnostic point types include two argillite Snook Kill blades, a chert Lamoka-like point, a chert Bradley Spike-like point, and a probable Excelsior-toed Stemmed point of argillite. The remainder consist of three untyped points manufactured from argillite and chert. One chert drill had a notched base highly consistent with the distinct base of an Otter Creek point. Two of the finds of FCR were entire cobbles reminiscent of boiling stones. Non-chipped items include a sandstone abradar, 446 pieces of FCR, a groundstone axe bit, five hammerstones, four manuports, a nutting stone, 64 pieces of raw material, two clamshell fragments, and three split cobbles (Table 11). Two soil anomalies (designated Features 3 and 4 in the field) were also identified at Block 4. Neither of these features contained artifacts, and their irregular morphologies were suggestive of natural root burns.

The pre-contact deposits at Block 4 appeared to be concentrated in two areas to the north along the workspace boundary, and to the west. The separate concentration areas are suggestive of repeated occupations that largely date to the Late Archaic period, based on the presence of the diagnostic points. Preliminary observations of the Block 4 assemblage indicate that there are a comparatively larger number of tools and tool types relative to other areas, as well as a higher ratio of tools to debitage. It was also noted that the Narrow-Stemmed points recovered from this area seemed smaller compared to those recovered from other areas, though additional analysis will be necessary to confirm this patterning. In either case, the assemblage is distinctly suggestive of processing activities likely associated with collection of resources, such as waterfowl, from the adjacent marsh.

Post-contact materials (N=1,438) recovered from Block 4 include ceramic sherds, glass, a lead musketball and piece of unidentified lead alloy, flint ballast, sheet copper, and a variety of personal items (Table 12). Ceramic types include redware, Staffordshire slipware, porcelain, creamware, ironstone, pearlware, earthenwares including tin enamel ware, whiteware, yellowware, and stonewares. Types of personal items consist of ball clay smoking pipe fragments, clothing fasteners of brass and copper, buttons, a clay marble, a strike-a-light of English flint, and gunflints. The age range of diagnostic materials from the post-contact assemblage largely spans the eighteenth and nineteenth centuries.

Block 5

Block 5 is located just south of Block 4 along the eastern side of the workspace and is comprised of 18 EUs (see Figure 4). A light lithic scatter of pre-contact materials was identified at this location during the Phase II evaluation. During the Phase III data recovery, two looter pits were identified within EUs 67 and 70. They appeared to be recent in origin, and were at first suspected to be archaeological test pits, but were too large and different in shape.

A total of 322 pieces of chipping debris, representing a variety of lithic materials, were recovered from Block 5. The debitage assemblage was dominated by argillite followed by jasper, chert and quartz (Table 13). Chipped stone tools consist of seven bifaces, two jasper cores, one drill, 48 projectile points, two quartz scrapers, and three utilized flakes (Table 14). Both of the cores were of jasper and at least one exhibited evidence of bipolar reduction. Of the projectile points, 45 were temporally diagnostic to a particular cultural period. One of the points was most consistent with the Dalton type, and could date to the Late PaleoIndian/Early Archaic period. Late Archaic point types include three argillite Narrow-Stemmed, and one quartzite Poplar Island-like point. The majority of projectile points recovered from Block 5 date to the later part of the Late Archaic to Transitional Archaic period, consisting of one jasper Susquehanna point, and 38 argillite Snook Kill blades. The majority of these latter points were recovered in situ from a cache feature described below. One argillite triangle point was also recovered that likely dates to the Late Woodland period. It is possible that the Susquehanna and Snook Kill points chronologically overlap with the Narrow-Stemmed points, though it was noted that the argillite Snook Kill blades exhibited very little weathering compared to the argillite Narrow-Stemmed points. Non-chipped stone items recovered from Block 5 include 444 pieces of FCR, two hammerstones, five manuports, 62 pieces of raw material, and 3 large fragment of a fire-cracked slab (Table 15).

Two features were encountered during excavation of Block 5 consisting of Feature 5 and Feature 8. Feature 5 consists of a soil anomaly first identified in EU 19 that could represent a possible pre-contact pit feature (see Figure 4). There were no visual indicators of a feature within B horizon soils below the plowzone, which is unsurprising given the sandy nature of the soils that are susceptible to extensive leaching. However, some such anomaly or feature was suspected to be present by excavators with the discovery of the large *in situ* slabs of fire-cracked rock that may represent cooking slabs (Photograph 1). The excavators subsequently observed a subtle difference in compaction and texture between the soils containing the *in situ* rock slabs and the surrounding soils. It was also noted that there was a very large amount of FCR in the overlying Apz within EUs 18 and 19 possibly associated with the cooking slab fragments and pit feature. Based on the subtle textural differences observed between the soil anomaly and surrounding soils, it was estimated that Feature 5 had a somewhat irregular oval shape measuring approximately 125-x-180-cm in plan and extended to 120 cmbs in depth. In profile, Feature 5 appeared to have a broad, sloping bowl-shaped morphology. In addition to the cooking slabs, pre-contact materials recovered from Feature 5 include chipping debris of argillite, chert, jasper, quartz, and quartzite, FCR, a hammerstone, a manuport, projectile points, and pieces of argillite and quartz raw material. Projectile point types include an untyped argillite, and two argillite Narrow-Stemmed points suggesting a Late Archaic temporal affiliation. Feature 5 may represent some type of pit feature, though based on the extremely sparse amount of charcoal, it is not thought to be a fire or cooking pit despite the large amount of FCR observed in the overlying plowzone. If Feature 5 does represent a pre-contact cultural feature, its function is uncertain at this time. Alternatively, Feature 5 could also be a result

of an ancient tree-throw. In either case, it is expected that processing of soil and other analytical samples may resolve its origin and function.

The second feature was designated Feature 8, and located within EUs 56 and 57 (see Figure 4). Feature 8 consisted of a cache of Snook Kill broadpoints or blades identified just below the plowzone in these units (Photograph 2). No edges of a cache pit were discernable within the surrounding B horizon due to leaching of the sandy soils over time. The size and observable use wear on the Snook Kill blades indicates that they were used as knives. A total of 25 blades were present *in situ* the cache, and their type indicates a Late to Transitional Archaic association. Some 13 other Snook Kill blades were recovered from the overlying plowzone in EUs 56, 57, and adjacent units. Past plowing at the site likely clipped the top of the cache scattering numerous blades into the surrounding plowzone.

A total of 799 pieces of post-contact material were recovered from Block 5 during the Phase III investigations (Table 16). Recovered material types include ceramic sherds, glass, pieces of flint ballast, pieces of sheet copper and sheet, a copper bullet, a lead musketball, and a variety of personal items. Ceramic types include redware, Staffordshire slipware, porcelain, earthenwares, creamware, pearlware, tin enamel wares, whiteware, yellowware, and stonewares. Personal items consist of ball clay smoking pipe fragments, a gunflint, and a clay marble. Diagnostic materials from the post-contact assemblage are dominated by items largely manufactured during the nineteenth century, though a small amount of items were manufactured during the eighteenth century.

Block 6

This Block is located south of Block 15 and north of Block 13 along the eastern side of the workspace (see Figure 4). A dense deposit of jasper debitage representing a lithic workshop area was identified in this area during the Phase II investigations, and Block 6 was situated to further explore this concentration of pre-contact materials. In all, a total of 30 EUs were excavated at Block 6.

Seven soil anomalies were identified in Block 6. Three of the anomalies, designated Features 9, 12 and 16 in the field, were determined to not be cultural in origin during excavation. The Feature 9 soil anomaly, located in EU 35 (see Figure 4), consisted of a narrow, deep deposit of organic soils that extended 135 cmbs at which point an intact mass of decaying tree roots was encountered. As such, Feature 9 was determined to represent tree remains, and is not considered cultural in origin. The soil anomaly designated Feature 12 was first identified as a large patch of reddish soil within the B horizon below the plowzone that extended across portion of EUs 37, 60, 65, and 66 (see Figure 4). Continuing excavation revealed that the horizontal and vertical morphology of the reddish soils was highly irregular, and that these soils, and the underlying sediments had been redeposited. It was concluded that Feature 12 consisted of a large, ancient tree throw that pulled subsoils higher up into the soil column, and what was suspected to be fire-reddened soils of cultural origin were in fact redeposited B₂ soils that generally had a redder appearance than the overlying B₁ horizon soils. The third soil anomaly in EU 95, designated Feature 16 in the field, was subsequently determined to be bioturbation related to rodent tunneling. The remaining four features consisted of two pre-contact fire pits and two post-contact post molds, and are described in further detail below.

A total of 4,036 pieces of pre-contact cultural material were recovered from Block 6, the majority of which consisted of debitage (N=3,251). A variety of lithic material types is represented in the debitage assemblage including argillite, basaltic rock, chalcedony, chert, granitic rock, jasper, quartz, quartzite, sandstone and shale (Table 17). Jasper was by far the most frequently occurring material. Substantial amounts of argillite, chert, and quartzite chipping debris were also present. The majority of the quartzite debitage consists of a coarse grained, metamorphosed quartzite. This same material is also well-represented among the FCR described further below.

A total of 43 chipped stone tools were also recovered from Block 6 and included eight bifaces, three cores, two drills, a graver, six performs, eight projectile points, four unifaces, nine utilized flakes, and two worked cobbles (Table 18). The bifaces were manufactured from various materials including argillite, chert, jasper and quartz. One of the quartz bifaces consists of a large chopper. The two jasper cores both consist of unidirectional core fragments and the remaining quartzite core exhibits evidence of bipolar reduction. Five of the projectile points had diagnostic characteristics. These points include a jasper Susquehanna point, a possible Twombly side-notched point of jasper, a possible chert Taconic Stemmed point, a quartz Triangle, and a chert point most consistent with the Wading River tradition. These points indicate the presence of Late Archaic to Transitional Archaic, and Late Woodland occupations. Non-chipped stone artifacts include a sandstone abradar, a groundstone axe, 521 pieces of FCR, five hammerstones, 11 manuports, a pestle, 201 pieces of various types of raw material, and an incised sandstone slab (Table 19). As noted above, a substantial amount of the FCR consists of a coarse-grained metamorphosed quartzite. Some of the pieces of FCR also looked flaked. This material comprised a substantial portion of the chipping debris as well. It may be that some of the FCR was opportunistically used for lithic manufacture.

Two pre-contact fire pits, designated Features 7 and 10 were also identified. Feature 7 was located in the southwest quad of EU 35 and was first observed just below the plowzone at 35 cmbs. In plan, Feature 7 measured 55-x-48-cm in maximum horizontal dimensions and exhibited a regular round morphology. Stained soils excavated as Feature 7 extended to 145 cmbs, though the actual bottom of the feature itself likely extends no deeper than 100 cmbs based on its morphology in profile. In profile, the feature exhibits a narrow, conical profile and becomes more irregular below this, which is likely due to leaching. Feature 7 yielded flakes of argillite (N=2), jasper (N=10), and quartzite (N=1) (see Table 17). Two sizeable charred logs were also present that were positioned vertically along the south side of the pit. A C14 sample from one of the logs produced a conventional radiocarbon age of 860 ± 30 B.P. (uncal.), dating to the early part of the Late Woodland period. Feature 7 is interpreted as the remains of a fire pit.

Feature 10 was first observed along the south edge of EU 38 at 55 cmbs, and consisted of an anomalous patch of reddened, charcoal-flecked soil. Adjacent EU 58 was subsequently opened up to fully expose the anomaly. As fully exposed, Feature 10 exhibited a somewhat irregular ovate shape in plan measuring 74-x-54-cm. The feature was shallow extending only 9 cm in depth and exhibiting a bowl-shaped profile. Feature 10 yielded one flake each of jasper and chert, and a sample of charcoal which will be submitted for radiocarbon dating. The feature is interpreted as the probable remains of a fire pit or hearth that has been severely truncated by plowing.

The pre-contact deposits at Block 6 consist of multiple, overlapping occupation episodes that date to the Late to Transitional Archaic period and Late Woodland period based on the presence of diagnostic artifacts and a radiocarbon date from Feature 7. Preliminary observations of the pre-contact deposits at Block 6 indicate that a large percentage of the deposits consist of an activity area

specific to lithic manufacturing of jasper, or a lithic workshop. Several of the jasper artifacts at Block 6 consist of cores, performs and expedient flake tools. In addition, a substantial amount of the jasper debitage was noted as exhibiting cortex. The jasper assemblage is suggestive of primary reduction from cobble sources of jasper, likely local in origin. The argillite debitage appeared more frequently along the eastern and southern sides of Block 6, and may indicate a separate lithic workshop loci. Flakes of granite and sandstone, as well as what appears to be an unfinished pecked axe were present at the northern end of Block 6, which may indicate the edge of a separate area related to groundstone tool manufacture and/or maintenance.

Post-contact deposits at Block 6 consist of two postmolds and 3,368 artifacts. Another soil anomaly was present consisting of two narrow, linear patches of dark, organic soil spaced approximately 4.5 ft apart and oriented in an east-west direction across EUs 34, 37, 59 and 60. The trees present in this area are younger than in adjacent areas, and it is suspected that this was an area cleared and possibly used as a construction staging area related to Goethal's Road to the south. Based on the size, spacing and presence of post-contact material including a piece of tire rubber, it was concluded that this soil anomaly consisted of a pair of tire ruts that pushed Apz soils deeper into the underlying B horizon. The two postmolds (Features 11 and 14) were both located in the southern portion of Block 6 (see Figure 4), and exhibited rectilinear, or squared shapes in plan. Feature 11, identified along the boundary of EUs 34 and 59 after removal of plowed soils, measured 25-x-27-cm in plan and extended 4 cm in depth. A piece of curved glass was recovered from the postmold. Feature 14 was identified along the south edge of EU 60. The postmold had a pointed profile that visibly extended through the plowzone to a depth of 46 cmbs. Feature 14 also yielded a piece of glass. The two postmold may represent the remains of a fence constructed after plowing at the site ceased.

The cultural material assemblage from Block 6 includes ceramic sherds, glass, ammunition, and a variety of miscellaneous and personal items (Table 20). Ceramic sherds types include redware, earthenwares, porcelain, creamware, ironstone, pearlware, tin enamel ware, whiteware, yellowware, and stonewares. Ammunition types include a lead bullet and lead musketball. Personal items include ball clay smoking pipe fragments, a copper alloy clothing fastener and probable shoe grommet, beads of clear and black glass, a severely corroded copper penny, two clay marbles, and buttons of copper, glass, and Bakelite. One of the Smoking pipe fragments exhibited a reddish-brown slip. Other items present include a piece of copper wire, pieces of flint ballast including one piece that appears to have been worked, and a gunflint. In all the diagnostic post-contact material from Block 6 exhibit dates ranging from the eighteenth to nineteenth centuries.

Block 7

Ten EUs were excavated at Block 7 situated at the location of a low density lithic scatter identified during the Phase II evaluation. The block is located near the center of the workspace 20 m south of Block 1 (see Figure 4). Pre-contact cultural materials recovered from Block 7 numbered 214 artifacts and include a chert biface, debitage, 43 pieces of FCR, three hammerstones, six manuports, projectile points, and nine pieces of raw material (Table 21). The debitage assemblage consists of 149 pieces of chipping debris. The debitage was produced from a variety of lithic material, though the assemblage predominantly consists of chert. One of the sandstone manuports exhibited incising possibly indicating the item was used as an expedient "abrader". One complete projectile point and two point fragments that refit were recovered. All of the points have been manufactured from chert. The point fragments represent a stemmed point most consistent with the Taconic stemmed tradition.

The complete point has been identified as a Late Archaic Narrow-Stemmed, though it also shares some morphological characteristics with the Taconic stemmed point tradition. The pre-contact deposits from Block 7 indicate the presence of more than one occupation likely related to temporary hunting camps.

Post-contact materials recovered from Block 7 include ceramic sherds, glass, a piece of flint ballast, pieces of copper sheet, a copper alloy handle, and a variety of personal items that in all totaled 1,261 items (Table 22). Types of ceramics included in the Block 7 assemblage are redware, porcelain, creamware, ironstone, pearlware, tin enamel ware, earthenwares, whiteware, yellowware, and stonewares. Personal items include ball clay smoking pipe fragments, buttons or other clothing fasteners, a thimble, a metal spoon, and a porcelain marble. Of particular note was a curved piece of copper sheet that appears to have been cut from a larger piece, scored and incised, and rehammered. This copper item may represent a piece of trade metal reworked by Native Americans, suggestive of a Contact period association. Diagnostic post-contact materials from Block 7 were largely manufactured during the late eighteenth to early nineteenth century, though a small amount of material appears to date to the earlier part of the eighteenth century.

Blocks 8, 9, 10, and 11

Blocks 8, 9, 10, and 11 are all located within the western portion of the Goethals Bridge HDD workspace, and each is comprised of three EUs (see Figure 4). Block 8 is situated at the location of a light lithic scatter identified during Phase II evaluation. A soil anomaly designated Feature 13 in the field was identified at 40 cmbs in the northwest quadrant of EU 64. The anomaly consisted of an irregular ovate area of organic mottled soil measuring 37-x-30-cm in plan and extended 40 cm in depth. The profile of the anomaly was distinctly slanted and appeared to contain redeposited topsoils and subsoils. No artifacts or charcoal was present in anomaly soils, though decomposing wood fragments were present. The anomaly is not considered to be cultural in origin, and has an appearance consistent with tree remains.

Pre-contact deposits at Block 8 consist of a low density lithic scatter comprised of 10 pieces of debitage, seven pieces of FCR, a hammerstone, four manuports, a projectile point, and 10 pieces of raw material (Table 23). As elsewhere, a variety of lithic materials was present in the debitage assemblage, with chert being the most frequently occurring material. The single projectile point consists of an argillite Narrow-Stemmed dating to the Late Archaic period. The Block 8 assemblage is consistent with short-term occupations, such as hunting camps. The presence of the Narrow-Stemmed projectile point indicates a Late Archaic period affiliation.

Post-contact materials recovered from Block 8 consist of ceramic sherds, glass, coins, ball clay smoking pipe fragments, an unidentified copper alloy tool, and a piece of flint ballast (Table 24). Ceramic sherd types include redware, slipware, earthenwares, porcelain, creamware, ironstone, pearlware, whiteware, yellowware, and stonewares. The coins recovered consist of an “Indian Head” penny that could date between 1859 and 1909, and a Buffalo nickel that could date between 1913 and 1938. In general, the diagnostic ceramics from Block 8 exhibit manufacturing date ranges extending through the eighteenth and nineteenth centuries.

A low density lithic concentration identified during the Phase II evaluation is the location of Blocks 9 and 10. Pre-contact materials recovered from Block 9 totaled 80 items, and include 37 pieces of debitage, 36 pieces of FCR, an argillite Bare Island projectile point, four pieces of argillite raw

material, an argillite utilized flake and a chert split cobble (Table 25). The debitage assemblage from Block 9 is dominated by argillite. A total of 409 pieces of post contact material were recovered from Block 9 consisting of ceramic sherds, glass, a piece of iron hardware, a copper button, and ball clay smoking pipe fragments (Table 26).

Pre-contact materials from Block 10 consist of 24 pieces of debitage, one quartzite core, 11 pieces of FCR, one manuport, one possible stone pendant, and six pieces of raw material (Table 27). Chert and argillite were the most frequently occurring lithic types in the debitage assemblage. Post-contact materials from Block 10 include 253 items consisting of ceramic sherds, glass, a U.S. mercury dime that could date from 1916 to 1945, ball clay smoking pipe fragments, and a gunflint (Table 28).

The pre-contact deposits at Blocks 9 and 10 consist of a low density lithic scatter representing one or more occupations likely dating to the Late Archaic period based on the presence of the Late Archaic Bare Island point. The deposits likely represent the remains of a short term camp where hunting, stone manufacture and/or maintenance, and limited processing activities took place. Diagnostic post-contact materials from Blocks 9 and 10 largely consist of eighteenth and nineteenth century materials.

Block 11 was situated at the location of Phase II EU 2 which produced a light concentration of pre-contact cultural material and evidence of possible postmolds that yielded Contact period and Middle Woodland radiocarbon dates of 330 ± 30 B.P. and 1340 ± 30 B.P., respectively. Pre-contact materials recovered from Block 11 during the Phase III data recovery consist of a small amount of debitage, 2 pieces of FCR, a groundstone tool fragment, a jasper projectile point and two pieces of argillite raw material (Table 29). Debitage material types include chalcedony, chert, and jasper. The projectile point is an untyped stemmed base fragment of jasper. Numerous small patches of dark, organic soil were observed in the B soils just below the plowzone. Given the presence of tree stumps at the surface, and numerous roots in the Apz and B soils, and lack of any discernable patterning, it was determined that the patches of dark organic soil represented bioturbation related to tree roots and were not cultural in origin. No additional postmolds were identified, and based on the observations of the Phase III EUs, it is now believed that the possible "postmolds" identified during the Phase II investigations are natural in origin as well.

Post-contact materials recovered from Block 11 consist of ceramic sherds, glass, and personal items (Table 30). In all, 448 pieces of post-contact material were recovered. Types of ceramic sherds include redware, terra cotta flower pot fragments, porcelain, creamware, earthenwares, whiteware, yellowware, and stonewares. Personal items consist of ball clay smoking pipe fragments, a copper alloy button, and a glass marble. The diagnostic ceramics from the Block 11 assemblage range in date from the eighteenth and nineteenth centuries.

Block 12

Block 12 consists of three EUs situated in the southwest portion of the workspace some 18 m west of Block 13 (see Figure 4). Block 12 is situated on a slightly raised area that contains compacted soils noted during the Phase II evaluation. No pre-contact materials were identified in this area during the Phase II evaluation, but the proximity of the area to the area of structural remains to the east and compact soils suggested that the area could represent a post-contact activity area and potentially contain shaft features such as a well or privy.

Fifty-nine pre-contact artifacts consisting of debitage, FCR, projectile points, a split cobble, and pieces of raw material were recovered from Block 12 (Table 31). The debitage includes a variety of material dominated by chert, but also including argillite, chalcedony, jasper, quartz and quartzite. The two projectile points consist of a chert stemmed point highly consistent with the Piney Island type, and a Lamoka-like point of quartz. The pre-contact deposits at this location consist of a light lithic scatter likely representing one or more occupations. Based on the characteristics of the points, the deposits could date to the Late Archaic period. The occupations at this location appear to represent a temporary hunting camp, and/or outlier deposits associated with the denser pre-contact deposits observed to the northeast.

Recovered post-contact materials numbered 636, and included ceramic sherds, glass, ball clay smoking pipe fragments, and two buttons of ferrous and cuprous material (Table 32). Ceramic sherd types include redware, porcelain, creamware, pearlware, earthenwares, whiteware, yellowware, American stoneware, English Brown stoneware, and Rhenish stoneware. No evidence of shaft features was identified during the excavation of Block 12.

Block 13

Block 13 consists of eight EUs situated at the location of the razed structural remains in the southeast corner of the workspace (see Figure 4). Block 13 was laid out to further explore the concentration of pre-contact materials at this location that were identified during the Phase II evaluation, and to determine whether potential shaft features associated with the structural remains were present.

Pre-contact materials recovered from Block 13 include consist of 114 artifacts including debitage (N=87), a chert biface, one chert core, 1 chert graver, two chert flakes, 19 pieces of FCR, and three pieces of argillite raw material (Table 33). A variety of materials is present in the debitage assemblage, which is dominated by chert followed by argillite and jasper. All of the tools consist of chert as well. It was noted that pre-contact Native American materials were most frequent along the eastern edge of the workspace indicating that denser deposits are likely present outside and east of the workspace. The pre-contact deposits at Block 13 indicate the presence of one or more occupations. The assemblage is indicative of lithic manufacture and/or maintenance activities.

Post-contact materials recovered from Block 13 consist of 1,288 items recovered largely from Demolition fill and Apz contexts. The demolition fill consists of a layer of structural debris from the area of the razed structural remains that overlay plowed soils in this area. Recovered post-contact material includes ceramic sherds, glass, buttons, metal hardware, and ball clay smoking pipe fragments (Table 34). The extremely dense deposits of post-contact domestic material at this location are likely related to its proximity to the area of structural remains. The diagnostic materials from this area generally date to the eighteenth and nineteenth centuries, though it is expected that the bulk of the ceramic assemblage will date to the early part of the nineteenth century when the structure at this location was occupied.

Block 14

Block 14 is located in the northern portion of the workspace between Blocks 2 and 5, and was comprised of four EUs (see Figure 4). Block 14 was laid out and excavated to determine the spatial distribution of pre-contact materials between the concentrations identified at Blocks 2 and 14. Two

soil anomalies were identified that were designated Features 17 and 18 in the field. Feature 17 consists of a possible post-contact pit feature, and is further described below. The anomaly designated Feature 18, located in the northwest quadrant of EU 134 (see Figure 4) had irregular morphology in plan and profile. In profile, Feature 18 measured 45 cm in thickness, and large root casts were observed extending out from the south side of the anomaly. Based on its morphology and a lack of artifacts, it was concluded that Feature 18 does not represent a cultural feature and represents the remains of an old “tree cast”.

Pre-contact materials recovered from Block 14 consist of 43 pieces of debitage, a jasper core, eight pieces of FCR, four pieces of raw material, and a split cobble (Table 35). A variety of lithic material types were present in the debitage assemblage, of which jasper was the most frequently occurring material followed by argillite.

Post-contact deposits at Block 14 included Feature 17, and 275 artifacts. Feature 17 was first observed at 55 cmbs in the southwestern quadrant of EU 134, and consisted of an irregular round patch of organic sediments within B horizon soils that measured 30 cm across. A rodent run had impacted and ran through the top of the feature. Feature 17 exhibited a regular bowl-shaped profile with a round to flat base that extended 41 cm in depth. Artifacts recovered from Feature 17 consist of a piece of possible delft, or tin enamel ware, and a gunflint. The uppermost few centimeters of Feature 17 contained the gunflint, as well as a couple of fragments of coal. The presence of the coal is likely related to rodent-related bioturbation at the top of the feature, and could indicate that the gunflint was possibly redeposited as well. The piece of delft or tin enamel ware was recovered from undisturbed feature soils. Overall, the contents of Feature 17 suggest it may represent a Contact or early colonial period pit.

Post-contact artifacts recovered from Block 14 include 275 artifacts consisting of ceramic sherds, glass, ball clay smoking pipe fragments, a fragment of copper alloy chain, a glass bead, pieces of flint ballast, and the gunflint recovered from Feature 17 as noted above (Table 36). Ceramic types include redware, porcelain, creamware, pearlware, the piece of tin enamel ware recovered from Feature 17, earthenwares, whiteware, yellowware, and stonewares. The bead was manufactured from black glass and had a conical shape likely designed to be inset. In general, the diagnostic post-contact materials were largely comprised of items that were manufactured during the eighteenth and nineteenth centuries.

Block 15

Block 15 is situated along the eastern side of the workspace and contained 18 EUs. It was laid out and excavated between Block 5 to the north and Block 6 to the south to further explore the distribution of pre-contact materials between what appears to be a processing activity area to the north at Blocks 4 and 5, and a lithic manufacturing area to the south at Block 6 (see Figure 4). A soils anomaly designated Feature 19 in the field was observed in EU 141 below the plowzone at 25 cmbs. In plan, the anomaly exhibited an irregular round to ovate shape measuring 48-x-52-cm. It was noted during excavation that the sides of the feature expanded and contracted, and the profile revealed an irregular, narrow conical shape. The feature was determined to represent the remains of a burned tree based on its irregular morphology, and is not considered cultural in origin.

Pre-contact deposits at Block 15 consist of a cache feature (Feature 20) and 1,046 pieces of Native American cultural material. Feature 20 consists of an *in situ* cache of materials that was located in

the northwest quadrant of EU 20 below the plowzone at 25 cmbs (see Figure 4). The cache consisted of a tightly clustered deposit of three artifacts consisting of a hammerstone, a large quartzite quarry blank, and a sandstone adz, the bit of which may be unfinished (Photograph 3). Artifacts from Block 15 include debitage (N=608), chipped stone tools and non-chipped stone items. The debitage assemblage contains a variety of lithic materials types, of which the most frequently occurring is jasper, followed by argillite and chert (Table 37). It is suspected that the sandstone and basaltic material may be related to groundstone production.

Chipped stone items include 11 bifaces, a chopper, a jasper core, an argillite drill, three jasper preforms, five projectile points, one jasper scraper, six split cobbles, three unifaces, eight utilized flakes, and the large quartzite quarry blank from Feature 20 as noted above (Table 38). Diagnostic point types include Otter Creek and Susquehanna points, both manufactured from chert. The remaining points consist of untyped points of chert and quartz. The remaining pre-contact materials from Block 15 consist of a quartz crystal, 338 pieces of FCR, five hammerstones including the one from Feature 20, 13 manuports, 41 pieces of raw material, and the adz from Feature 20 (Table 39). The diagnostic artifacts from Block 15 suggest occupations dating from the Late Archaic and Transitional Archaic periods. The pre-contact assemblage as a whole is suggestive of processing and lithic manufacturing activities with a possible emphasis on the latter.

A total of 1,090 pieces of post-contact material was recovered from Block 15 consisting of ceramic sherds, glass, metal hardware items, pieces of flint ballast, a lead bullet, and a variety of personal items (Table 40). Ceramic sherd types include redware, Albany slipware, earthenwares, porcelain, creamware, ironstone, pearlware, tin enamel ware, whiteware, yellowware, and stonewares. Types of hardware, include a horsehoe, a washer of cuprous material, a lead grommet, and other miscellaneous hardware. Personal items include pieces of ball clay smoking pipes, clothing fasteners, a button, a slate pencil, and a flint strike-a-light. At least one of the smoking pipe fragments exhibited a reddish-brown slip. Of particular note was a piece of dark olive bottle glass, that appears to have been possibly reworked. Overall, the majority of the diagnostic post-contact materials from Block 15 were manufactured during the eighteenth to nineteenth centuries.

Blocks 16

Located just north of Block 18 and west of Block 15, Block 16 is made up of three EUs (see Figure 4). Pre-contact materials recovered from Block 16 consist of a jasper biface, an argillite Snook Kill Blade, debitage (N=61), 15 pieces of FCR, a manuport, two pieces of raw material, and piece of worked granite (Table 41). Jasper and chert were the most frequently occurring lithic material types among the Block 16 debitage assemblage. The Snook Kill blade is in relatively close proximity to the Snook Kill blade cache (Feature 8) identified in Block 5, and may have been displaced into the Apz at this location through plowing. The deposits at Block 16 are likely a continuation of the processing and lithic manufacturing deposits present at Blocks 5 and 15.

Post-contact materials recovered from Block 16 include ceramic sherds, glass, pieces of copper, ball clay smoking pipe fragments, a glass bead, and a remnant of a leather dog collar with attached metal New York City license (Table 42). A date of 1915 was discernable on the license. Also recovered was a dog ulna. The dog related remains were found together with a relatively large amount of ribbed and etched plate glass in the uppermost part of the plow stratum suggesting the presence of a small historic dumping episode.

Block 17

Block 17 is situated near grid coordinate N0E0 at the location of a small lithic concentration identified during the Phase II evaluation that included debitage and a biface of a distinctly green Normanskill chert (see Figure 4). This was the only location where this material was recovered during both the Phase II and Phase III excavations. This Block is comprised of three EUs. Fifty-eight pieces of pre-contact material were recovered from Block 17 consisting of 35 pieces of debitage, 18 pieces of FCR, a manuport, and four pieces of argillite raw material (Table 43). Chert was by far the most frequently occurring material type among the debitage from Block 17, which was largely comprised of the above-noted Normanskill chert. These deposits suggest a single occupation episode of late stage lithic manufacture.

Post-contact materials from Block 17 totaled 300 items consisting of ceramic sherds, glass, a glass button and ball clay smoking pipe fragments (Table 44). The post-contact materials from Block 17 generally range in date from the eighteenth through nineteenth centuries.

Block 18

Block 18 consists of five EUs located immediately west of Block 15 (see Figure 4). The units were excavated to further explore the extent of the concentration of pre-contact cultural materials at Block 15. Pre-contact materials recovered from Block 18 include four bifaces, debitage (N=181), two jasper cores, 54 pieces of FCR, a piece of calcined mammal bone, 11 manuports, three projectile points, 22 pieces of raw material, two split cobbles, a jasper uniface, and two utilized flakes (Table 45). A variety of lithic material types was present in the debitage assemblage, but jasper was by far the most frequently occurring material. Two of the manuports exhibited subtle battering, and one had clear abrasion marks suggestive of more specific functions. Of the three points, two were diagnostic consisting of a chert Susquehanna point and an argillite Snook Kill blade. The third point consists of an untyped chert stemmed point. Like adjacent Block 15, the artifacts are suggestive of processing and lithic manufacturing activities dating to the Late Archaic/Transitional Archaic periods.

A total of 385 pieces of post-contact cultural material were recovered from Block 18 including ceramics, glass, buttons, a slate pencil, pieces of flint ballast, and ball clay smoking pipe fragments (Table 46). One of the smoking pipe pieces consists of a bowl fragment with red bodied paste. This is possibly a colonial period pipe of American manufacture. Most of the diagnostic post-contact materials date to eighteenth and nineteenth century date ranges.

Blocks 19 and 20

Blocks 19 and 20 were excavated along the eastern edge of the workspace. Block 19 is situated east of Blocks 4 and 5, and Block 20 is east of Blocks 6 and 15 (see Figure 4). Each Block is composed of two EUs, and was excavated to determine and compare the distribution of materials down slope and closer to the wetland edge relative to the concentration of pre-contact materials observed in Blocks 4, 5, 6, 15 and 18.

The pre-contact materials from Block 19 totaled 57 artifacts consisting of debitage (N=30), 25 pieces of FCR, one piece of argillite raw material, and one argillite utilized flake. One piece of FCR had clearly been used as a hammerstone, and another as an abrader before subsequently becoming

fire-cracked (Table 47). The deposits at Block 19 appear to represent the outer eastern edge of the processing activity area observed at Blocks 4 and 5. Recovered post-contact materials from Block 19 include ceramic sherds, glass, and ball clay smoking pipe fragments (Table 48).

Pre-contact deposits (N=86) at Block 20 consist of debitage (N=41), 37 pieces of FCR, two groundstone tool fragments, three manuports, a jasper Susquehanna projectile point, one piece of argillite raw material and a coarse, grit-tempered aboriginal ceramic sherd (Table 49). The sherd is tempered with coarse grit, exhibits subtle cordmarking, and is most consistent with the Vinette I-type dating to the early Woodland period. The deposits at Block 20 could represent an eastward continuation or overlapping component of the deposits observed at Blocks 6 and 15. Post-contact cultural materials from Block 20 (N=317) consist of ceramic sherds, glass, a piece of flint ballast, a button, and ball clay smoking pipe fragments (Table 50).

EUs 46 and 171

EU 46 consist of a single 2-x-2-m unit located near the south edge of the workspace in proximity to Block 13 and the area of razed structural remains (see Figure 4). The placement of EU 46 was determined by the presence of a 100 cm diameter round depression that was suspected to possibly represent a potential shaft feature such as a well or privy. A small amount of pre-contact material (N=22) was recovered from EU 46 consisting of 14 pieces of debitage, two pieces of FCR, a Narrow Stemmed projectile point, and five pieces of argillite raw material (Table 51). Most of the debitage consists of argillite, and the presence of the Narrow Stemmed point indicates a Late Archaic occupation episode. Post-contact material recovered from EU 46 include ceramic sherds, glass, a glass marble and ball clay smoking pipe fragments (Table 52). Diagnostic materials from EU 46 largely consist of materials dating to the eighteenth and nineteenth centuries.

The depression consisted of a 30 cm-thick conical layer of redeposited soil which is most likely related to a natural tree throw. No evidence of a cultural shaft feature was present.

EU 171 is situated east of Block 6 and also consists of a single 2-x-2-m excavation unit (see Figure 4). A sparse amount of pre-contact cultural material was recovered consisting of three chert flakes and five pieces of FCR (Table 53). The sparse amount of material at this location demonstrates that the dense deposits associated with Block 6 do not continue to the west of the raised landform. Recovered post-contact materials include 78 items consisting of ceramic sherds, glass, and ball clay smoking pipe fragments.

Preliminary Interpretations

Diagnostic materials and the radiocarbon date processed thus far from the Phase III pre-contact assemblage indicate pre-contact period occupations spanning the Late Archaic through Late Woodland periods (ca. 6,000 to 450 B.P.). The presence of the Dalton point indicates the presence of at least one occupation dating as early as the late PaleoIndian/early Early Archaic period (ca. 9,000 B.P.). The vast majority (78 percent) of the diagnostic materials from the Old Place Neck Site consist of Late Archaic to Transitional Archaic materials (Narrow Stemmed points, Snook Kill blades, Lamoka points, Susquehanna points, Taconic Stemmed points, and a Wading River point). The bulk of the diagnostics dating to this time period consist of Narrow Stemmed points and Snook Kill blades, nearly all of which are manufactured from argillite. The Narrow Stemmed point

assemblage is consistent with Bare Island types, or what has been termed a Bare Island-Poplar Island intergrade at other sites on Staten Island (Lavin 1980, Williams 1968).

Only a handful of the diagnostic materials were attributable to the later Woodland period (Vnette I ceramic sherd, Levanna and small triangle points) suggesting the site was less intensively used during later periods. All radiocarbon dated features, however, including those from the Phase II evaluation have yielded Woodland period to Contact period dates. It is suspected that these features do not necessarily reflect longer term or more intensive occupations at the Old Place Neck Site. Instead, the types of features used during these later periods of occupation are deeper and have survived historic plowing that has occurred at the site. It is suspected that the large amount of FCR observed at the site likely reflects shallower fire pits or hearths that did not survive subsequent plowing. These shallower fire pits or hearths would have been used by the Late to Transitional Archaic occupants of the site.

A variety of lithic material types are represented in the chipping debris and stone tool assemblage, a substantial portion of which consists of argillite likely derived from the Lockatong formation in New Jersey. The use of this material is most likely associated with the Late to Transitional Archaic period of occupation given that the Narrow Stemmed points and Snook Kill blades are all almost exclusively manufactured from argillite. Late Archaic occupations at other sites on Staten Island largely consist of Narrow-stemmed Bare Island/Poplar Island components, and there is scarce evidence of occupation on Staten Island by Late Archaic Laurentian tradition producers (Lavin 1980; Ritchie 1969; Williams 1968). It has been suggested that this coupled with a distinct preference for argillite indicates that the Late Archaic occupants of Staten Island were culturally affiliated with Narrow-stemmed producers in New Jersey (Lavin 1980:28-29).

Chert and jasper were also used for the other point types at the site dating to this time period (e.g. Lamoka, Susquehanna, Wading River, Taconic-Stemmed). The vast majority of the chert at the site is morphologically consistent with Hudson River Valley source areas. Jasper at Middle Atlantic region sites is typically attributed to Pennsylvania source areas, though it is suspected that the jasper at the Old Place Neck Site was locally acquired. Local sources of jasper, likely in the form of glacially transported cobbles, were known to be present on Staten Island (Davis 1933, Hollick 1906, 1913, Rutsch 1968, 1970).

None of the deposits at the Old Place Neck Site are suggestive of longer term residential base camps. Site deposits within the central and western portion of the workspace are generally low density and reflect temporary camps affiliated with hunting and stone tool maintenance activities. In contrast, the deposits along the eastern side of the workspace appear to represent distinct activity areas largely confined to a low rise overlooking the wetland. The deposits to the northeast at Blocks 4 and 5 (see Figure 4) likely represent a processing area. Materials from this area include a large number of broken tools (e.g. bifaces, scrapers, utilized flakes) a dense concentration of FCR, numerous argillite Narrow Stemmed points, a nutting stone, probable cooking slab fragments, manuports (possibly used as net weights), and the large cache of Snook Kill blades. The deposits from this area suggest the site was visited on a seasonal basis for the collection and processing of marsh-related resources such as migratory waterfowl.

A second, distinct activity area consists of the lithic manufacturing area farther south along the low rise at Block 6 (see Figure 4). A large amount of chipping debris, particularly of jasper was recovered from this area (see Table 17). Substantial amounts of argillite, chert and quartz were also

present possibly indicating multiple loci, or episodes of lithic reduction. The jasper in particular frequently exhibits outer cobble cortex suggestive of primary stage of reduction. This in turn suggests that the jasper was likely acquired from locally available cobbles.

The other Block excavation areas in between these two distinct activity areas appear to represent areas of overlap between the processing and lithic manufacturing areas, although the emphasis on a preliminary basis appears to be on lithic manufacture and/or maintenance. Some of the lithic manufacturing activity may be related to groundstone manufacture/maintenance based on finds of worked pieces and debitage of granitic, sandstone and basaltic materials, and the cache containing the adz, hammerstone and a large quartzite quarry blank (Feature 20).

It is uncertain at this time whether these activity areas represent contemporaneous loci, or represent separate activity areas occupied by separate groups of people. The processing area, at the very least, was likely repeatedly visited on a seasonal basis, and the deposits at the lithic manufacturing area likely are the result of multiple episodes of occupation.

A Native American contact/early colonial period occupation at the site remains tentative at this time, though any such occupation is suspected to have been temporary and ephemeral. Evidence for a Native American contact/early colonial occupation includes pieces of flint (ship) ballast and pieces of copper. Numerous pieces of the flint ballast had a worked appearance, and many of the gunflints appear to have been expediently manufactured from pieces of ballast. Several additional pieces of sheet copper were also recovered during the Phase III data recovery, the most intriguing of which consists of the large incised piece of copper or brass from Block 7. Hammer marks are evident on the outer face of this piece suggestive of reworking. Metallographic analysis of the copper pieces may contribute more provenience information.

The majority of the diagnostic materials from the post-contact period assemblage exhibit eighteenth to nineteenth century date ranges of manufacture. The frequency of the post-contact material appears to correlate with the testing blocks' proximity to the area of the early nineteenth-century razed structural remains along the southeast corner of the workspace (see Figure 4). The majority of the assemblage appears to date to this time period, though additional review of the diagnostic assemblage will be necessary to confirm this pattern. No post-contact shaft features, such as wells, privies and refuse pits, were identified during the Phase III data recovery. It is suspected that any such features, if present at the site, lie outside of the workspace.

Recommendations

The results of the field investigations and preliminary analyses have indicated that the information collected from the Old Place Neck Site makes a significant contribution to the archaeological record of the New York City area. Much of what is known of the immediate region is largely based on secondary reports, artifacts collections, and the work of amateur archaeologists largely dating to the early twentieth century. As such, the character and contents of "previously recorded" archaeological sites in the area is poorly documented. The systematic excavations conducted at the Old Place Neck site yielded an extensive assemblage of data-rich deposits, and represent a rare opportunity for the professional excavation of an archaeological site in the New York City metropolitan area. Overall the archaeological investigations at the Old Place Neck Site have resulted in a substantial sample (10.06 percent) of the portion of the site that lies in the Goethals Bridge HDD workspace.

It is therefore recommended that the portion of the Old Place Neck Site within the Goethals Bridge HDD workspace be cleared so that the proposed construction activities can proceed as planned.

Avoidance Measures

To mitigate the potential for inadvertent construction-related impacts to the portions of the Old Place Neck Site that lie outside of the Goethals Bridge HDD workspace and not subject to the data recovery program, orange safety fencing will be erected along the edge of the construction right-of-way throughout the remaining portions of the site area. The cultural resource training that all construction workers will attend prior to construction activities will identify these areas as exclusion areas.

Completion of Outstanding Tasks

Remaining tasks to be completed include more detailed analysis of artifacts, features and samples, the technical report, and the public education component of the data recovery program.

Analyses

More detailed analysis of the artifact assemblage will be undertaken. Types of artifact analysis that will be conducted include an examination of the spatial distribution of materials, processing and examination of soil flotation samples as appropriate, and lithic analysis involving an examination of the stone tools for use wear. More specialized analyses will also be undertaken that include analysis of residues (e.g. protein, phytoliths, etc.) as appropriate, and metallurgical analysis of copper items that are suspected to be affiliated with a Contact period or early colonial period Native American occupation. Additional samples collected for radiocarbon dating will be prepared and submitted to Beta Analytic for processing. The additional analyses are expected to yield a substantial amount of data that will contribute to a greater understanding of the site occupation(s) and complexity.

Technical Report

A draft technical report will be produced after the completion of the specialized cultural material analyses described above. The report will conform to the guidelines set forth by the FERC (2002), New York SHPO (2005), NYAC (1994), LPC (2002) and the National Park Service in the *Recovery of Scientific, Prehistoric, Historic, and Archaeological Data*, 36 CFR Part 66 Appendix A. Draft copies of the report will be submitted for review and comments by the client and appropriate agencies. The completed final technical report will follow the draft review. The New York SHPO and LPC will be provided four paper copies (two bound, one unbound) of the final report as well as a PDF copy on CD. Five copies of the report will also be provided on CD for local libraries and other historical associations. The draft technical report will be submitted within 12 months following the submittal of the clearance memorandum, as stipulated in the Programmatic Agreement. A final report will be submitted within 60 days of receipt of written comments by the client, the FERC, the New York SHPO, LPC and any other consulting parties.

Public Education

An important aspect of the Phase III data recovery program will be outreach to and education for the public, especially those with an active interest in the Native American past of New York City.

Efforts to be undertaken for this portion of the data recovery program include construction of a web page with video documentation, presentations on the site designed for public, as well as professional audiences, development of lesson plans to be used in the Staten Island public school system, and the development of an informational brochure geared towards the general public.

The development of an informational web page within Spectra Energy's company website and related video documentation are currently ongoing. The web page will present the results of the archaeological investigations in an engaging and interactive format, and has the potential to reach a wide audience. Some of the video documentation has already been completed by a professional videographer who took footage of the fieldwork (crew interviews, excavations) and of laboratory-related activities at the on-site facility.

Presentations to the general public will also be undertaken and could consist of a lecture and slide show/PowerPoint presentation of the results and analyses at the Old Place Neck Site. The lecture could be coordinated with the Professional Archaeologists of New York City (PANYC), Staten Island Museum, and/or Staten Island Historical Society in order to reach a wider public audience. Any public presentation would be coordinated with Spectra Energy and those tribes that have requested ongoing consultation regarding the NJ-NY Expansion Project. Preparation of a presentation for a professional audience at a meeting such as the Society for American Archaeology, or for New York Archaeology Month will also be completed. Publication of the results of the data recovery program in a popular publication and in a regional or other appropriate journal is also possible.

The preparation of a brochure that discusses the archaeological findings at the Old Place Neck Site in the context of Native American lifeways in the lower Hudson region will also be completed. The brochure will be written for an audience consisting of the general public. Spectra Energy shall provide a copy of the draft brochure to the New York SHPO, LPC, interested Native American tribes or organizations, the Staten Island Museum, for review and comment, and these comments shall be taken into account to finalize and print the brochure. Copies of the final brochure (and a compact disk containing a PDF file of the final brochure) shall be provided to the New York SHPO and LPC for their archives and for these agencies to distribute to other libraries, archives, and other interested groups or individuals. This brochure will also be made available in PDF format for download from the Phase III program web page to be designed through Spectra's website as described above.
